Foreword

The present *Socio-Economic Atlas of Kenya* is one of several reports developed based on the *2009 Kenya Population and Housing Census* data set. It arrives at a crucial development juncture, following the development of the Second Medium Term Plan (2013–2017) and the upcoming post-2015 Sustainable Development Goals agenda. The development and implementation of these national development plans and other strategies will benefit greatly from the depiction and deep analysis of socio-economic indicators in this atlas.

It is important to note from the outset that a number of other highly informative reports have been developed using data from the *2009 Kenya Population and Housing Census*. The Kenya National Bureau of Statistics has produced a number of specific reports, most notably 13 monographs covering topics such as population distribution (four volumes); population dynamics and projections; migration; urbanization; labour dynamics; housing, amenities, and assets; education; disability; and gender dimensions. The Bureau has also published a *National Census Atlas*, and will soon publish a volume on the spatial dimensions of well-being. However, the present socio-economic atlas differs from these other publications in terms of its structure, its format of data application and presentation, and its high spatial resolution.

As noted, the atlas uses a high degree of spatial resolution to vividly illustrate the factors that define and influence the standards of living and coexistence of Kenyan citizens. It depicts Kenya's geographic and socio-economic characteristics and how they vary by location and at various levels.

It can be inferred from this atlas that Kenya has made great achievements in all spheres of life over the past half-century, particularly in combatting poverty, ignorance, and disease. Overall, Kenya has registered significant milestones in improving the general welfare of its citizens. Various government initiatives have been implemented to improve the welfare of Kenyans through targeted resource allocation at lower levels of governance. These initiatives include the Constituency Development Fund, the Orphans and Vulnerable Children (OVC) programme, the recent allocation of county budgets, and the Uwezo Fund. Education infra-

structure, facilities, and enrolment at all levels have improved significantly, and today over 90% of Kenyans have some formal education. The health sector has also made great strides, as evidenced by the growing concentration of health facilities and improved ratios of health workers to patients, bringing health services closer to the people and ensuring high-quality service delivery.

This socio-economic atlas represents an invaluable resource for those in charge of devising development initiatives at both the national and the county government levels. The disaggregation of indicators in the atlas will provide fact-based insights for both levels of government. The atlas illuminates a broad range of indicators that will inform targeting, monitoring, and evaluation. County governments, in particular, will find the atlas highly useful as a planning and policy tool, as they strive to fulfil their critical functions and steer development processes at devolved levels. This product is therefore well suited to the needs of governors and their support teams – county assemblies, county executive committees, and sub-county administrators.

Further, the structure and format of the atlas is tailored to provide insights for both governments and the private sector. It is a good source of general information for the representatives of the commercial and non-commercial private sector, as well as for the broader public, who can utilize it as a valuable source of evidence to support specific development debates and decisions.

Structurally, the atlas brings together various policy fields and topics, integrating them in a single volume. It enables comparison across the various fields and topics, which include population characteristics and dynamics, water and sanitation, household assets, levels of poverty and education, and economic activities. These aspects are presented in an innovative format: the maps display population characteristics at the sub-location level, using symbols that indicate the size of the population. This has distinct advantages over maps that use shaded areas, which can create a misleading visual impression. In this way, the maps offer detailed insights into local conditions, giving readers precise information on where exactly particular circumstances prevail and how many people are affected.

Based on these two unique principles of clear structure and high-resolution maps, the authors offer important fact-based insights that reflect their own interpretations and understanding, without limiting readers' freedom to derive their own insights and draw their own conclusions. By structuring, interpreting, and presenting census data in this manner, the present atlas provides a strong basis for tracking Kenya's further progress and documenting new changes that will be reflected in the next national population census in 2019.

At this crucial juncture in Kenya's political, social, and economic development focusing on the transformation of the country, this atlas arrives at the right time and equipped to inform planning, decision-making, policy formulation, and subsequent implementation of the national policies and strategies.

Eng. Peter Oganga Mangiti

Ministry of Devolution and Planning

Acknowledgements

Compilation of the *Socio-Economic Atlas of Kenya* was a true team effort involving dedicated staff from three organizations: the Kenya National Bureau of Statistics (KNBS), the Nanyuki-based Centre for Training and Integrated Research in ASAL Development (CETRAD), and the Centre for Development and Environment (CDE) at the University of Bern, Switzerland.

Following joint development of the initial project idea, sub-location-level data for each atlas theme were extracted from the original *2009 Kenya Population and Housing Census*. The data were then harmonized and mapped at high resolution. We wish to thank Paul Waweru, George Kamula, and Emma Odhiambo (KNBS), who did this with expert precision while simultaneously fulfilling various data requests from the teams working on individual atlas themes.

A chapter dealing with poverty and welfare was planned from the outset. However, this required combining the 2009 census data with data from household surveys by means of a complex modelling approach. Paul Samoei and Samuel Kipruto (KNBS) worked closely with Michael Epprecht (CDE), developing and implementing the model, eventually generating poverty and welfare estimates at the sub-location level. While developing the model in an iterative process, Paul Samoei and Samuel Kipruto played key roles in harmonizing data and coordinating KNBS's contributions with the teams from CETRAD and CDE. We greatly appreciate their invaluable contributions.

The atlas contains additional information – integrated to ease interpretation of findings – which was not derived from the 2009 census. This includes information on climate, land cover, rivers, parks, roads, and other aspects. Evanson Njuguna and Elizah Peter (CETRAD) compiled the information from various sources, including CETRAD and CDE's joint database, and then harmonized it with the spatial references used in the atlas. We are very grateful for their dedicated work and their good collaboration with the teams from CDE and KNBS.

While developing the atlas, members of all three institutions helped elaborate its themes and topics by critically reviewing data, putting findings into context, and formulating insights and interpretations. We particularly wish to thank Mary Wanyonyi, Vivianne Nyarunda, Rosemary Bowen, and Henry Osoro (KNBS), as well as Cordula Ott and Silvia Lörcher (CDE) for their crucial contributions in this process.

Our very special thanks go to Matthias Engesser and Lilian Trechsel (CDE). In addition to coordinating and harmonizing the database and the overall project workflow together with KNBS and CETRAD, they analysed the data for every map and graph and finally produced each component using sophisticated GIS software, in close and continuous collaboration with the authors. Without their hard work and dedication, the atlas would not have been published.

At different stages of production, external reviewers made valuable comments on one or several atlas themes. We especially wish to thank Geoffrey K. Ndenge (UNICEF), Jane W. Kabubo-Mariara (UON), Michael Bowen (Daystar University), Eldah Onsomu (KIPPRA), Andrew Mutuku (UON), George Odipo (UON), Robert K. Nderitu (KNBS), Zachary Gariy (JKUAT), and Hanspeter Liniger (CDE) for their respective inputs. Further, we wish to thank Lorenz Hurni (ETHZ) for his important advice in the field of cartography.

We are also very grateful to our team of editors: Marlène Thibault, Anu Lannen, and Tina Hirschbuehl Hufschmid (CDE), as well as Robert Blasiak (University of Tokyo), Erin Gleeson (SciencEdit.CH), and Evie Dovaston (Textmax GmbH). Their thorough editing and harmonization of texts benefited the atlas immensely. Further, we wish to express our warm thanks to Simone Kummer, who developed and implemented the layout of the atlas together with Matthias Engesser and Lilian Trechsel. We also wish to thank Stefan Zach of z.a.ch GmbH for proof-reading, the team at Rubmedia for their helpful advice and excellent printing, and Schumacher AG for binding this volume.

We gratefully acknowledge funding from the Department of Integrative Geography and CDE, both of the University of Bern, as well as the Eastern and Southern Africa Partnership Programme (ESAPP), the Swiss National Centre of Competence in Research (NCCR) North-South, and the Volkswagen Foundation. The funds received from these sources were pooled and managed under the watchful eyes of CETRAD's Accounts Department, for which we would like to thank the team involved, especially Jacinta Muchugu for her supervisory role.

We are also very thankful for the general logistical support we received from our mother institutions – KNBS, CDE, and CETRAD – as well as the enabling environment facilitated by the Government of Kenya through the Ministry of Devolution and Planning and the Ministry of Environment, Water and Natural Resources.

Last but not least, we wish to thank our families and friends for their wonderful support throughout the entire process.

Urs Wiesmann
Boniface Kiteme
Zachary Mwangi

Introduction & Background

Introduction

This socio-economic atlas is a special gift to all Kenyans as they celebrate the 50th anniversary of the Republic of Kenya. In the five decades since independence, Kenya's population has increased by a factor of four; at the same time, the country has developed rapidly in many socio-economic fields, lifting it from a development to a transition country. This atlas illustrates the great achievements made and, at the same time, helps identify fields where further improvements are desirable.

Since 2010 the Republic of Kenya has a new Constitution that defines a new interplay between the levels of the national government and the governance structures of 47 newly founded counties, which are both committed to sustainable and equitable development. This atlas is designed to serve both levels of governance by displaying information at scales adequate to either of them, thereby promoting informed decision-making and planning. At the same time, the atlas aims to enhance the knowledge of Kenya's citizens and the broader public regarding the diversity of situations and developments in this fascinating country.

This atlas is the result of a unique institutional collaboration between the Kenya National Bureau of Statistics (KNBS), the Centre for Training and Research in ASAL Development (CETRAD), and the Centre for Development and Environment (CDE) at the University of Bern, Switzerland. KNBS hosts the best available socio-economic data in the country, CETRAD has decades of experience in integrating research and development, and CDE has long-standing collaborative links with Kenya and considerable experience in producing such an atlas. By joining their respective expertise, these institutions have embarked on an innovative process that has made this atlas possible.

The atlas mainly depicts the results of the 2009 National Population and Housing Census, but it also refers to other surveys and is enriched with some additional thematic layers (see sources in the respective chapters). The idea for this atlas was conceptualized shortly after the census results were released, but the actual work on the atlas began in 2012, when the main census reports – notably the 13 monographs – were being developed. The present atlas is intended to supplement these other releases from the 2009 census by emphasizing the spatial variation of the main findings.

This atlas is unique in several respects, namely its spatial resolution, its population-centred display, its combined thematic foci and its emphasis on relative values for pattern detection. These four unique characteristics are discussed briefly here:

(1) High-resolution maps with two distinct spatial levels

The aim of this atlas is to serve both the national government and the county governments. The presentation of the data therefore follows administrative units. Although comparative county figures may serve most purposes at the national level, county governments require higher-resolution data about their territories. The sub-location, the smallest administrative unit available, is therefore the best spatial reference. This atlas combines a high-resolution display of the 7,149 sub-locations in Kenya with aggregated data for the 47 counties. These two spatial reference systems are systematically used in all themes and maps, thereby enabling comparisons between all themes and maps.

(2) Population-centred display

The problem of many conventional maps depicting population characteristics is that they use area shading, meaning that an area with certain population characteristics is shaded in a certain colour. This may be very misleading in a country like Kenya, where population densities vary greatly between vast arid pastoralist zones, high-potential agricultural areas, and urban settings, because the shading of a large area with a small population may make a greater visual impression than a town with one million inhabitants. To avoid this problem, this atlas does not use area shading, but instead applies a population-centred display. This display depicts sub-locations by means of proportional symbols which indicate the size of the population in the given sub-location. These symbols – instead of the sub-locations' areas – are shaded to display the information depicted on the given map. All maps in this atlas contain enlarged insets to enable this type of display in densely populated areas and major towns. By applying these principles throughout the atlas, sub-locations across the country are displayed with equal visual weight.

(3) Combining different thematic foci in a comparative manner

This atlas covers a comprehensive range of six main themes relevant to development. Five of these themes are taken directly from the 2009 census. The theme on population distribution and dynamics is covered in chapter 2 and includes 14 maps that dwell on population densities, basic demographic factors, and sociocultural diversity. Water, sanitation, and energy are addressed in eight maps in chapter 3, focusing on access to safe water, sanitation, and different forms of energy. House-

hold assets (eight maps) are reviewed in chapter 4, which touches on housing, transport means, and information and communication technology. Chapter 6 tackles the subject of education in nine maps that highlight primary and secondary school attendance rates and touch on the overall education levels reached by the adult population. Chapter 7 (seven maps) discusses employment rates and aspects of the labour force from multiple perspectives.

The final theme is poverty and welfare; it was addressed by combining data from the *2009 Kenya Population and Housing Census* and the *Kenyan Integrated Household Budget Survey 2005/06*. This theme, which is covered in seven maps in chapter 5, addresses poverty and welfare at the high-resolution, sub-location level. Some additional information on spatial characteristics is also provided in this chapter. By standardizing the way data are presented across all six themes, we have made it possible to compare information for any given area.

(4) Emphasis on relative values for pattern detection

In the five years since the census, some absolute figures will have changed. Therefore, this atlas seeks to discourage readers from focusing too closely on absolute population numbers down to the single person, and indicates these numbers in thousands at the county level and in millions at the national level. Indeed, the emphasis of the atlas is on relative figures, such as proportions of the total population, as these relative figures will remain relevant for a longer time than the absolute values. The use of relative values also enables the detection of patterns that hint at underpinning processes and dynamics. Some of these patterns are highlighted in the texts accompanying each map, with the goal of instigating further discussion and evaluation. Similarly, each map is accompanied by a graph that shows the relative distributions among rural and urban contexts, as the rural–urban gradient has proven to be important in most themes.

These four characteristics make this atlas a unique and valuable complement to the other products stemming from the 2009 census.

This introductory chapter gives background information for the optimal use of the atlas and its six themes. It contains nine maps that are clustered into three groups:

Maps 1.01 and 1.02 give an introduction to the geography of Kenya and to the counties as basic reference units. These two maps are mainly addressed to readers who are less familiar with Kenya.

Maps 1.03 to 1.05 deal in more detail with the principles of this atlas. They explain the different components of the standardized layout by showing the considerations behind the population-centred display, and by highlighting the methodology behind the standardized display of the rural–urban dimension that accompanies every map. These three maps are relevant for everyone who wishes to develop a deeper understanding of the advantages and limitations of the approaches used in this atlas.

Maps 1.06 to 1.09 display topical background information that may be useful for interpreting the maps on the six themes. These include the agroclimatic zones that are crucial for understanding the population distribution; a rough land-cover map that illustrates the relationship between ecological conditions and land use; information on the distribution of forests and parks as important conservation areas, as well as on the extent of the large river basins that link counties through upstream–downstream relations; and finally, transport systems and accessibilities that to a large degree mould centre–periphery patterns. These four maps are addressed to readers who want to link observations in the thematic maps with potential causal factors.

Thus, this atlas is intended not only as an information tool, but also as a tool for developing informative conclusions through the creative combination of its contents. Ideally, this atlas will be used by readers interested in and working for the development of this fascinating country, and particularly by governments concerned with sustainable and equitable development at both the national and the county levels.

1.01 Geographical Overview of Kenya

The Republic of Kenya is a fascinating country with rich geographical features as well as diverse sociocultural and physical settings. Remarkable landmarks and expansive landscapes shaped by nature provide a home to over forty tribes and a range of languages that extend across the length and width of Kenya's 592,586 km². Kenya is neighboured by Tanzania to the southeast, Uganda to the west, South Sudan and Ethiopia to the north, and Somalia to the east.

The map shown here is derived from MODIS satellite imagery and hints at the diversity of the country. Greenish colours show high-potential zones where the majority of Kenyans live, while greyish to reddish colours indicate the vast arid and semi-arid zones. The map provides geographical context and shows the country's location on the equator. For additional orientation, the names of major towns and settlements are indicated, as well as some of the names of rivers that arise in the wet regions and nourish drier zones. The map also identifies the 47 newly designated counties that form a core reference point for this atlas. This satellite image map, however, is insufficient for completely showing the country's diversity. Therefore a brief overview of some of its major features is given here. The reader may wish to consult a higher-resolution map to locate the names given in this overview.

The country extends from the low-altitude coastal belt of the Indian Ocean in the southeast and gradually the elevation rises to just above 1,000 m above sea level before flattening along the extended length of the Yatta Plateau. The monotony of the flat plains is intermittently broken by residual hills, namely the Taita and Kyullu Hills, which are masses of broken boulders and inselbergs of the Kibwezi–Makindu line. The Yatta Plateau is flanked by the rising Mbooni and Machakos Hills to the west, where the elevation gradually drops down to the Tana River before climbing rapidly to form the Central Highlands. These reach an imposing 5,200 m above sea level to form the country's most spectacular snow-capped national landmark, Mount Kenya. To the west, the Aberdare ranges rise to just over 4,000 m above sea level. These two landmarks form one of the most important water towers in the country.

The Great Rift Valley, which enters Kenya from its southwestern neighbour, Tanzania, continues on to its northern neighbour, Ethiopia, and divides the Kenyan highlands into east and west, creating another very striking feature of Kenya's geography. The Kenyan highlands comprise one of the country's breadbaskets owing to the highly reliable precipitation and

fertile soils. Livestock is raised here and it is also where the most successful large- and smallholder commercial farming is practised, with crops including tea, coffee, pyrethrum, wheat, and maize.

The western highlands separate the Lake region from the rest of the country, and stretch from Kisii in the south to the tea plantation areas of Kericho, before continuing through to Kitale, Eldoret, and further north to elevations 4,300 m above sea level. This is where the impressive Mount Elgon rises up, the product of an extinct volcano. These highlands are also known for their high agricultural potential, making them the second of Kenya's main breadbaskets.

In addition to Lake Victoria, Kenya is well endowed with small and large lakes, which dot the floor of the Rift Valley from Lake Amboseli in the south to Lake Turkana in the north. Lake Turkana, the "jade sea", crosses into Ethiopia at its northern end and is the world's largest desert lake. Lake Victoria, on the other hand, is the world's second-largest freshwater lake, and is shared by Kenya, Uganda, and Tanzania. The lake basin is dominated by the Kano plains, which are suitable for farming through irrigation.

The northern and northeastern parts of Kenya are dominated by arid plains and several isolated mountains, most notably the Mathew and Ndoti ranges, Mount Marsabit and its beautiful Lake Paradise. The Songot Mountains, Murua Ngithigerr Laima, Lokwonamoru, and Lorionestom are found in the central, northern, and northwestern corners of Turkana. These isolated hills and mountains enjoy higher levels of precipitation, and thereby become crucial areas for resource concentration. Consequently they represent convergence zones for both humans and livestock, especially those in search of water and pasture. Furthermore, numerous seasonal rivers and streams, which are important for distributing water to the much drier areas in the lowlands, are fed by sources in these hills and mountains, especially during rainy seasons.

The southern rangelands border Tanzania. They stretch from the Lolgorien Hills through the Nguruman Escarpment, the Maasai Mara, and the Namanga Hills to end in the southeastern corner of Kajiado, where they are bounded by the Kyullu Hills to the east and the northeastern slopes of Mount Kilimanjaro to the south. The isolated hills of Lolgorien, the Nguruman Escarpment, and Namanga are also important grazing and watering areas during dry seasons. The southern rangelands are rich in both

livestock and wildlife resources, and are famous for the Maasai Mara game reserve, which forms one part of the monumental wildebeest migration along with the Serengeti National Park in Tanzania.

Kenya's coastal area is its major tourist attraction due to its beautiful and extensive beaches, first class tourist hotels, marine parks, and good weather that prevails throughout the year. The region has a lot to offer including its rich and largely intact culture and landmarks such as the Mombasa deep water Kilindini port, the national oil refinery, and the famous Fort Jesus. Further north, the coast has even more attractions like the Malindi wonders, which include one of Kenya's great unknown treasures, the thick canopy of the only surviving indigenous Arabuko Sokoke forest. This is also where one finds the Vasco Da Gama Pillar, which is over 500 years old, the Watamu and Malindi marine parks that open onto idyllic sandy beaches, and Hell's Kitchen a few kilometres to the north of Malindi. Further north, Lamu Island is home to one of the oldest and best-preserved Swahili settlements in East Africa. The town is almost devoid of motorized transport, and is traced by just alleyways and footpaths, making it no surprise that it has been listed as a World Cultural Heritage Site.

Kenya's advantageous geographical location makes it the gateway to East Africa and a global travel hub. It is a crossroads for trade and communication, serving eastern and central Africa as well as the Horn of Africa. The capital city Nairobi is the regional commercial hub, while Mombasa is the largest port and serves the entire East African hinterland.

All local and foreign trade and travel policies and legislation should therefore strive to facilitate the best possible conditions for reaping and preserving the potential provided by this rich geography.

1.03 Map Layout in This Atlas

This atlas aims to make detailed socio-economic information available to the public. More importantly, it aims at providing relevant information and analyses from Kenya's 2009 census to decision-makers and planners – particularly those working in the first and second levels of government established by the new Constitution of Kenya in 2010.

The sub-national overviews and comparative county-level information in this atlas will likely be of interest to people working at the level of the central government. Those involved in planning and decision-making at the county level will likely appreciate having easy access to information on the variation and distribution of relevant indicators within counties. To that end, the atlas presents data at the level of individual sub-locations, the smallest units that can be meaningfully depicted based on Kenya's 2009 census.

To meet the needs at both levels of governance, Kenya's 47 counties and its 7,149 sub-locations form the core spatial reference units of this atlas. Each section of the atlas is comprised of five components arranged side-by-side across two pages. These components – including maps, texts, graphs, and tables – are presented in the same layout each time to ease comparison. They are described in detail below.

The main map (odd page numbers)

Providing the desired degree of detail at the sub-location level posed a challenge to the scale and layout of the atlas. The size and population density of Kenya's counties and sub-locations vary greatly due to the country's rich diversity of geographical contexts rooted in the range of ecological belts (from arid and semi-arid to high-potential) as well as in historical developments. Depicting densely populated urban agglomerations by their individual sub-locations was particularly challenging.

To represent all contexts adequately, the main map consists of the following components:

1. *Kenya map*: The map at the centre of the page represents Kenya at a scale of 1:4,000,000. At this scale the sub-locations in less densely populated regions of Kenya are clearly visible. The map also provides an overview of the highly populated areas, but without each sub-location being clearly identifiable.

2. *Map insets for central and western Kenya*: Two map insets at a scale of 1:2,500,000 zoom in on the densely populated areas of central Kenya and western Kenya, which are home to about three-quarters of Kenya's population. The insets, both of identical size, are placed to the right and left of the country map. In the insets, most sub-locations in rural settings are clearly identifiable; sub-locations can also be identified, though less clearly, in most smaller to medium-sized towns.

3. *Map insets for Nairobi and Mombasa*: Two further map insets show Nairobi and Mombasa at a scale of 1:600,000 and allow urban sub-locations in these two counties to be identified. The insets cover the same surface area and thus illustrate the differences in size and density between the largest and second-largest cities in Kenya.

Map 1.03 shows the extent and position of the four map insets on the Kenya map. All maps in this atlas include the Kenya map with the four insets, with the exception of maps 1.01 (geographical overview) and 2.02 and 2.03 (demographic variables that cannot be disaggregated to the sub-location level). However, the positioning of the insets on the Kenya map is not repeated.

In order to enable navigation of the maps of this atlas, the Kenya map and its insets are overlaid by a digital terrain model and show national, county, and sub-location borders as well as major waterbodies and major conservation areas (i.e. national parks). However, the names of counties, major towns and settlements, and waterbodies are not repeated on the thematic maps of this atlas. To see these names, readers are asked to refer back to the maps in this introductory chapter (especially maps 1.01 and 1.02). The key to repeated elements is found on the right side below the insets, while the key to elements that change for each map is positioned to the left.

When texts refer to the main map, this includes the Kenya map and the four insets that show sub-location values at the scales mentioned above.

County map (even page numbers)

Unlike in this introductory chapter, all maps in chapters 2 to 7 are accompanied by a map at a scale of 1:11,500,000 in the lower right corner of the evenly numbered page, that shows the respective themes at the county level. By displaying average values

per county, this map provides a national overview. Contrary to the main map, which uses proportional symbols representing the population size of sub-locations (see map 1.04), the county map uses no symbols but displays the average values per county in conventional area shading (choropleth map). The colour scheme and classes used in the county maps are identical with those in the main maps. This enables readers to easily compare county averages with the details displayed in the main map, e.g. to see what varying sub-location values result in the county average. The smaller reproduction of the county maps is also used in the content tables of each chapter to enable easy orientation.

In the texts, the map displaying county averages in national overview is generally referred to as county map.

County table (even page numbers)

This atlas does not aim to provide detailed statistics of the 2009 census, as these have been or will be published by the Kenya National Bureau of Statistics in other formats. Instead, it is designed to provide information on the variation of relevant census data at the county level (see county map) and the sub-location level (see main map). However, information on the themes displayed in this atlas may still be of interest, especially at the county and national levels. For this reason, each map includes a table in the third column of evenly numbered pages (or, in the case of this introductory chapter, in the fourth column) that displays concrete figures and information related to the theme of the map for each county and for Kenya as a whole. These tables are referred to as county tables in the texts. They all display the counties in the same order, so readers can always find the county of interest in the same row. This order follows the sequence of counties as they are listed in Kenya's 2010 Constitution, except that the capital, Nairobi, has been shifted from the bottom to the top row. The last row gives the overall figures for Kenya, making it an important reference for interpreting the respective map. The first two columns show the county name and average of the variable displayed on the map. Further columns give additional information relevant to the displayed theme. Most maps show relative values (e.g. percentage of the population). To complement these relative values, absolute numbers (e.g. how many people) were added in the county tables. It is important to note that all figures for absolute values per county of households or persons are given in thousands. This was done deliberately to show the wider dimension rather than an exact figure for each and every household and person.

Rural–urban graph (even page numbers)

Analyses have shown that many themes displayed in this atlas are strongly influenced by rural–urban gradients. For this reason, all maps in chapters 2 to 7 are accompanied by a graph illustrating the differences between rural and urban areas. In each case, this graph is placed above the county map and referred to in the texts as rural–urban graph. Section 1.05 explain these graphs in more detail.

Texts (odd page numbers)

The first two columns contain a text explaining and commenting the map at hand. It normally starts by justifying the relevance of the theme displayed, followed by methodological explanations where needed. Then the overall national figures are explained and commented, followed by observations, comments, and interpretations of the variations shown at the county and sub-location levels, and ending with some general conclusions. It is important to note that these texts provide facts and background, but that the interpretation of these facts is done by the authors of this atlas. Readers should feel free to make additional observations based on the rich information displayed, and to draw additional or other conclusions than those of the authors. In that sense, the texts are intended to provoke further interpretation and discussion of the findings presented in this atlas.

Water, Sanitation & Energy

Introduction

Water, sanitation, and energy are key requirements for a decent standard of living. This presupposes that households have access to safe water for human consumption and household use, organized and safe human waste disposal, and energy sources for basic household functions. In addition, all three requirements interrelate closely with the natural environment and natural resources by relying on the provision of ecosystem services and by influencing ecological dynamics and conditions. The Government of Kenya therefore gives these sectors high priority in a broad range of policy fields, such as in the Water Act of 2002 and, more recently, in Kenya's *Vision 2030*, in conjunction with international conventions and initiatives such as the Millennium Development Goals.

Against this background, this chapter examines the three sectors of water, sanitation, and energy from the perspective of Kenya's 8.8 million households. It highlights whether, to what degree, and where in the country households have access to safe water, sanitation facilities, and energy sources. This household-centred perspective does not include any assessment of the state of the three sectors' supply side in terms of natural resources and infrastructure. The chapter is grouped into three parts – one for each sector.

Maps 3.01 to 3.03 deal with access to safe water. In the 2009 census, households were asked about their main domestic water source; their answers form the basis for this evaluation. The maps show the location of the sources and whether they are considered "safe" or "unsafe" under World Health Organization (WHO) guidelines.

Map 3.01 shows the proportion of households in counties and sub-locations with access to a safe water source. The map reveals that 56% of all households have access to safe water: this means that 3.85 million households have no access. Access rates vary greatly along ecological, economic, and rural–urban gradients; the map indicates areas where improvement is most urgently needed.

Map 3.02 establishes which source of water is most commonly used by households with access to safe water. Piped water is the most dominant source, followed by boreholes and protected springs. Protected wells also play an important role, while rainwater harvesting has a supplementary function.

Map 3.03 shows unsafe water sources most commonly used by households with no access to safe water. In urban settings, water vendors are the most dominant source. In many rural areas, streams and rivers are the main source, indicating the importance of watershed management. Knowing the location of heavily used unprotected wells and springs will facilitate targeted improvement of unsafe water sources.

Maps 3.04 and 3.05 deal with access to improved sanitation facilities that reduce risks associated with the incorrect disposal of human waste. The 2009 census established the types of sanitation facility primarily used by individual households. Following WHO guidelines, these were classified into "improved" and "unimproved" facilities, forming the basis for the sanitation-related maps.

Map 3.04 displays the percentage of households in counties and sub-locations with access to improved sanitation facilities. Overall, 65% of Kenyan households have access to improved sanitation. While considerable, this rate varies greatly by sub-location and partly mirrors population densities. Problematic areas requiring special attention are those with low improved sanitation rates and high population densities, found in rural as well as urban settings.

Map 3.05 specifies the most commonly used sanitation facilities, improved and unimproved, in different parts of the country. It illustrates that main sewers and septic tanks remain confined to larger urban centres and that covered latrines are the most common safe facility in rural settings. It also reveals that uncovered latrines and open defecation ("bush") are widespread in many parts of the country, but especially critical in densely populated areas.

Maps 3.06 to 3.08 illustrate the main energy sources used by households for the two basic functions of cooking and lighting. Based on the 2009 census results, the maps highlight important aspects of Kenyan households' use of solid biofuels, fossil fuels (e.g. in the form of paraffin), and electricity.

Map 3.06 shows the percentage of households in counties and sub-locations that mainly use solid biofuels for cooking. Solid biofuels include direct use of biomass such as wood from trees and shrubs, grass and crop residues, dung, and biomass transformed into charcoal. Overall, 82.5% or 7.2 million households still rely on solid biofuels for cooking, while only a minor

ity, mainly in urban areas, use other sources such as paraffin, gas, or electricity. At 17%, charcoal plays a role in and around urban centres, while firewood still remains the main energy source for cooking for 64% of Kenyan households.

Map 3.07 illustrates the use of fossil fuels in the form of paraffin for lighting. It reveals that more than two-thirds (69.5%) or 6.1 million of all Kenyan households use paraffin as their main energy source for lighting. The spatial distribution suggests that this high percentage can be interpreted as a transitional phenomenon in the absence of alternatives, especially electricity.

Map 3.08 thus illustrates the use of electricity for lighting by households. Overall, 23% or almost one in four households use electricity for lighting, a comparatively high figure in the East African context. However, the spatial distribution reveals that the use of electricity remains mainly confined to urban settings; the agglomeration of Nairobi is home to roughly half of all households using this energy source.

Together, the maps presented in this chapter paint a picture of Kenya that is in rapid transition, with fairly steep centre–periphery and urban–rural gradients. These developments affect the water, sanitation, and energy sectors, and cause households to transform their respective strategies. The maps reveal the regions in which these sectors have reached good standards and where special efforts may still be required.
